The Milky Way in Molecular Clouds

The Milky Way and its nearest neighbors, the Andromeda galaxy (M31) and the Large Magellanic Cloud (LMC), are shown in the top panel. The color scale represents the CO line intensity, with red indicating the highest intensity. The inset boxes show the M31 and LMC regions. The bottom panel shows the CO line intensity map with a color bar on the right indicating intensity in K km/s. The color bar ranges from -180 to +300.

The bottom map shows the distribution of the CO line intensity, with a color bar on the right indicating intensity in K km/s. The color bar ranges from -180 to +300. The top map shows the CO line intensity map with a color bar on the right indicating intensity in K km/s. The color bar ranges from -180 to +300.

Top map: $\log I_{CO} \text{ (K km s}^{-1}\text{)}$

ABSTRACT

The all-Galaxy CO survey of Dame et al. is by far the most uniform, large-scale Galactic CO survey. Using a dendrogram-based decomposition of this survey, we present a catalog of 1064 massive molecular clouds throughout the Galactic plane. This catalog contains 2.5×10^8 solar masses, or $25^{+10.7}_{-5.8}$ % of the Milky Way's estimated H_2 mass. We track clouds in some spiral arms through multiple quadrants. The power index of Larson's first law, the size-linewidth relation, is consistent with 0.5 in all regions—possibly due to an observational bias—but clouds in the inner Galaxy systematically have significantly ($\sim 30\%$) higher linewidths at a given size, indicating that their linewidths are set in part by the Galactic environment. The mass functions of clouds in the inner Galaxy versus the outer Galaxy are both qualitatively and quantitatively distinct. The inner Galaxy mass spectrum is best described by a truncated power law with a power index of $\gamma = -1.6 \pm 0.1$ and an upper truncation mass of $M_0 = (1.0 \pm 0.2) \times 10^7 M_\odot$, while the outer Galaxy mass spectrum is better described by a non-truncating power law with $\gamma = -2.2 \pm 0.1$ and an upper mass of $M_0 = (1.5 \pm 0.5) \times 10^6 M_\odot$, indicating that the inner Galaxy is able to form and host substantially more massive GMCs than the outer Galaxy. Additionally, we have simulated how the Milky Way would appear in CO from extragalactic perspectives, for comparison with CO maps of other galaxies.

Key words: Galaxy: general – ISM: clouds – ISM: molecules

“IAU Milky Way”, est. 1959

True Milky Way, modern

The equatorial plane of the new co-ordinate system must of necessity pass through the sun. It is a fortunate circumstance that, within the observational uncertainty, both the sun and Sagittarius A lie in the mean plane of the Galaxy as determined from the hydrogen observations. If the sun had not been so placed, points in the mean plane would not lie on the galactic equator. *[Blaauw et al. 1959]*

The Physical Properties of Large-Scale Galactic Filaments

Catherine Zucker, Alyssa Goodman, Cara Battersby
Harvard-Smithsonian Center for Astrophysics

catherine.zucker@cfa.harvard.edu

#48

Nessie is a "Bone" of the Milky Way

1 The infrared dark cloud "Nessie" seen in extinction. Its length (160+ pc) and aspect ratio (>300:1) suggests its formation is due to the global spiral potential of the Galaxy.

2 Nessie lies within 3 pc of the physical Galactic midplane (dashed colored line), at $d=3.1$ kpc

3 Nessie's velocity gradient exactly matches the global spiral fit to the Scutum Centaurus Arm in p-v space

And it may have friends!

4 Milky Way Bones: Ultra-dense, high aspect ratio Nessie analogs that may form the "Skeleton" of the Milky Way. Analogs must satisfy quantitative Bone criteria (Zucker+2015)

Nessie Analog from Zucker+2015

2.3 Establishing "Bone" Criteria
After narrowing down our list to 10 filaments with kinematic structure consistent with existing spiral arm models, we develop a set of criteria for an object to be called a "bone".

1. Largely continuous mid-infrared extinction feature
2. Parallel to the Galactic plane, to within 30°
3. Within 20 pc of the physical Galactic mid-plane, assuming a flat galaxy
4. Within 10 km s^{-1} of the global-log spiral fit to any Milky Way arm
5. No abrupt shifts in velocity (of more than 3 km s^{-1} per 10 pc) within extinction feature
6. Projected aspect ratio $\geq 50:1$

Ragan+2014

6 Large-Scale Herschel Filaments: Dense, cold filaments (aspect ratios $\gg 10$) chosen through visual inspection of Hi-GAL images. Confirmed velocity contiguous through ^{13}CO GRS data (Wang+2015)

Wang+2015

5 Giant Molecular Filaments: 70+ pc lower density filaments traced mainly by ^{13}CO , with typical aspect ratios between 5:1-10:1 (Ragan+2014, Abreu-Vicente+2016)

7 MST Bones: Filaments created by connecting dense BGPS $\text{N}_2\text{H}^+/\text{HCO}^+$ sources in p-p-v space using Minimum Spanning Tree algorithm. Must also satisfy additional Bone criteria based on Zucker+2015 criteria (Wang+2016)

Wang+2016

But they have different properties and utility in tracing spiral structure

8 Size Scale Comparison of Large-Scale Filament Catalogs: Herschel column density map with filament outlines overlaid

9 Filament Venn Diagram: Only 18% of large-scale filaments share any overlap with other large-scale filament catalogs

10 Systematic offsets in column density (top left), temperature (top right), scale height (bottom left) and position angle (bottom right) among different classes

But they have different properties and utility in tracing spiral structure

Milky Way 3D Galactic Plane Coverage Tool

MilkyWay3D.org is a tool intended to organize and curate links to information about data sets relevant to our 3D understanding of the Milky Way. For any given longitude range, we provide the means to determine the available surveys, their overlapping footprint, and the type of data each provides. Information about each dataset, including how to access the data, their hallmark publications, and their principal investigators, is available at the Milky Way 3D Dataverse. All the data can be loaded, "linked", and explored using the new 3D visualization software package Glueviz, available for download at glueviz.org/

ABSTRACT

After studying how line width depends on spatial scale in low-mass star-forming regions, we propose that “dense cores” (Myers & Benson 1983) represent an inner scale of a self-similar process that characterizes larger scale molecular clouds.

FIG. 10.—An illustration of the transition to coherence. Color and shading schematically represent velocity and density in this figure. On large scales, material (labeled chaff) is distributed in a self-similar fashion, and its filling factor is low. On scales smaller than some fiducial radius, the filling factor of gas increases substantially, and a coherent dense core, which is not self-similar, is formed. Due to limitations in the authors' drawing ability, the figure emphasizes a particular size scale in the chaff, which should actually exhibit self-similar structure on all scales ranging from the size of an entire molecular cloud complex down to a coherent core.
